VIRTUAL WORLD FRAMEWORK

Rob Chadwick (Katmai Support Services)
Allison Corey (Lockheed Martin)

What is VWF?

- ⦿ The Virtual World Framework (VWF) is a fast, light-weight, web-based architecture for creating and distributing, scalable, collaborative, and component-based virtual spaces.
- ⦿ When an application is designed to use the VWF, the architecture automatically handles the replication and synchronization between clients, allowing the application to be shared by multiple users

Design Philosophy

- ◎ Embrace HTML5 and web-based standards
 - Execute simulations on multiple platforms
 - Ensure future compatibility
 - Enable integration with other technologies
- ◎ Embrace open source technology
 - Avoid vendor lock in
 - Leverage the community of users to develop the platform
 - Need a feature or have an improvement? Build it! Submit it!
 - Allow users to branch and modify the platform for their own needs

Design Philosophy

- ◎ Use JavaScript for simulation logic
 - There are millions of web developers in the world. It's accessible and easy to learn
 - Performance is quickly improving, and is acceptable for many use cases
 - Development time is greatly reduced relative to other languages
 - Modify simulation logic in real time, while the system runs
- ◎ Use 'replicated computation'
 - Run all logic on client machines. The architecture ensures synchronization
 - Very low server overhead. One server can run many simulations

System Overview

VWF Architecture and Design

- ◎ Highly modular design
 - Users can add capabilities at several levels
 - Components – reusable simulation objects
 - Drivers – Provide services and features
 - Model Drivers participate directly in the simulation, for instance the physics driver must modify the position of objects
 - View Drivers inject input and display the simulation. We currently provide drivers for the ThreeJS and GLGE rendering systems.

VWF Architecture cont.

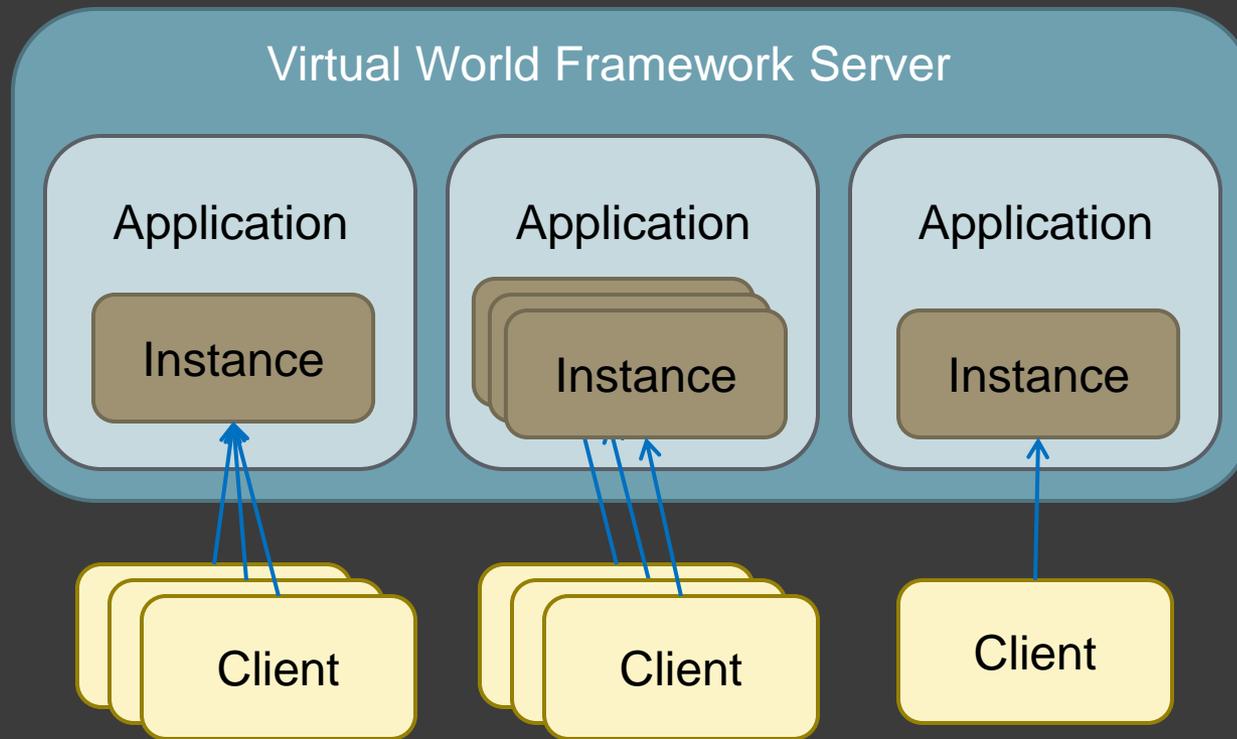

⦿ Low bandwidth

- Only inputs into the simulation are sent over the network
- Logic and behavior are executed locally on each client
- Separation of the simulation code from the view and input guarantees that clients remain in sync, even when there are no network updates

⦿ Simple server

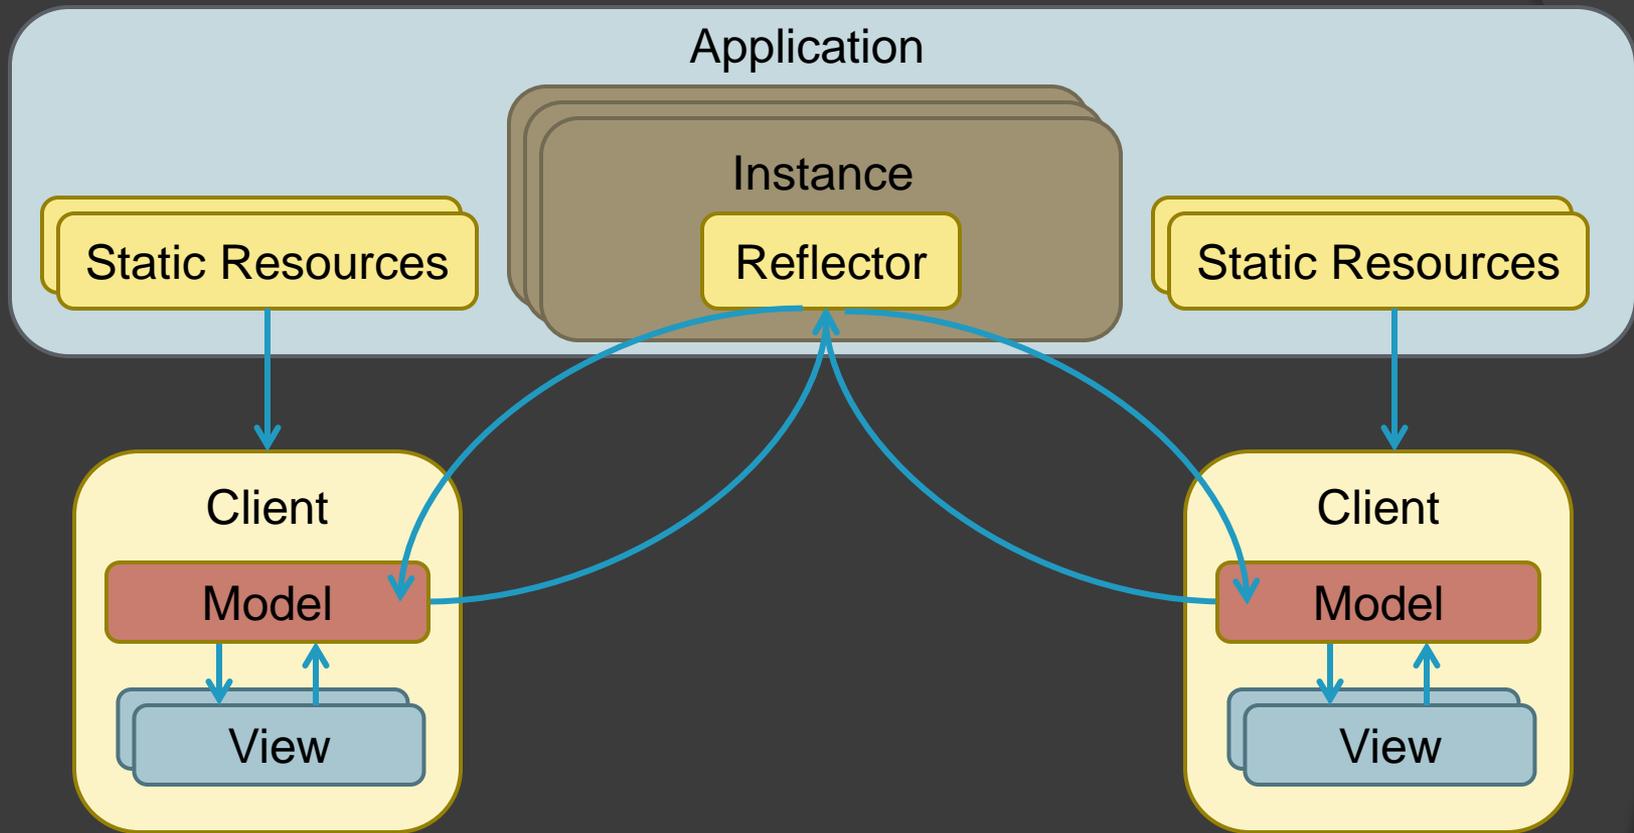

- The server is simply a web host for HTML resources, and a reflector for messages
- Server can run many applications concurrently

Server Architecture

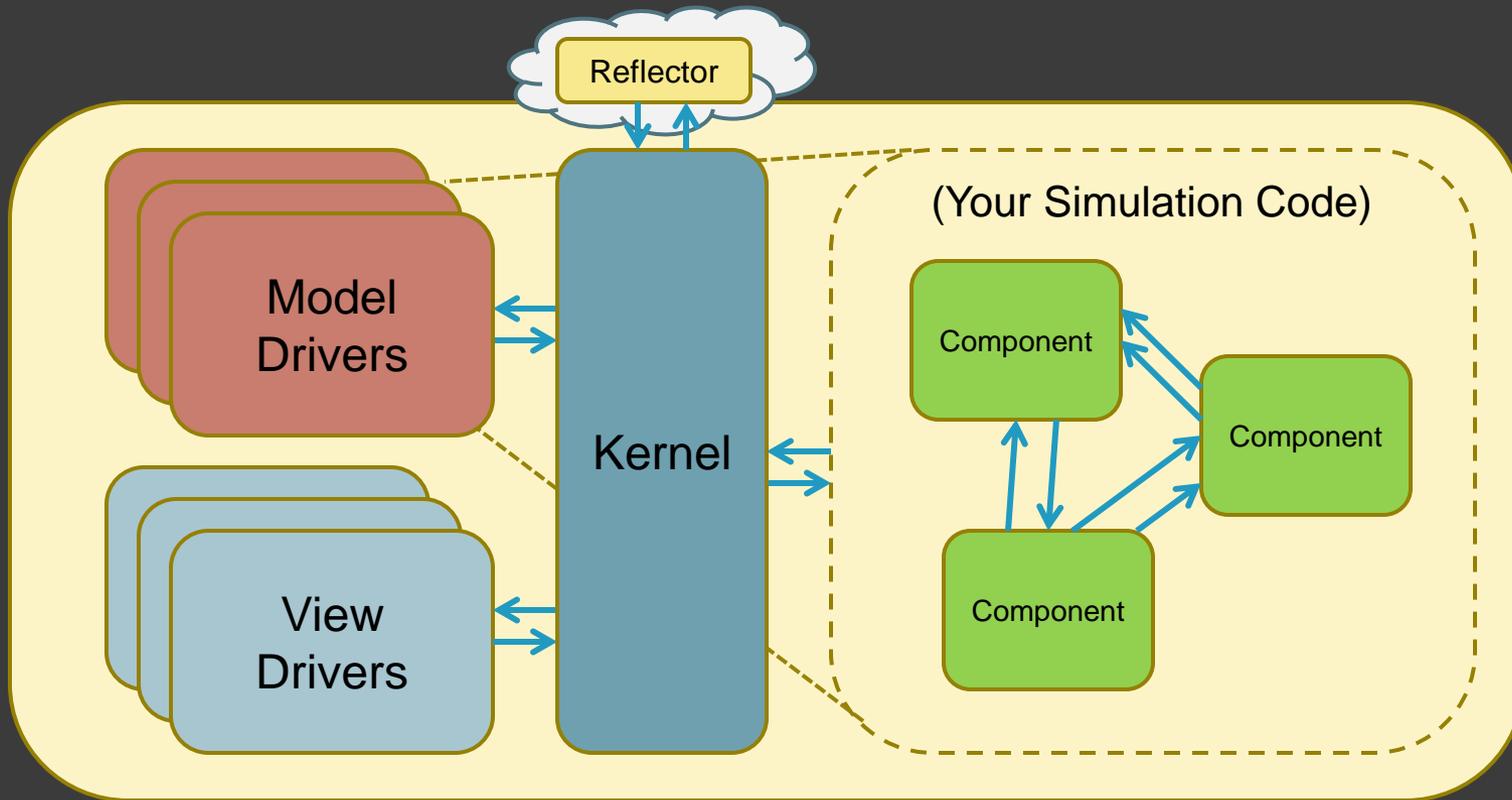

- A VWF server can host many applications
- Each application can have multiple instances running at once
- Clients connect to a specific instance of an application

Anatomy of a VWF Application

- Each client connects to a given instance of an application
- The server creates a 'reflector' for each instance.
- Whenever a simulation changes its internal state, the reflector synchronizes the other clients
- The view is responsible for displaying the data contained in the model

Inside a VWF Client

- The VWF system contains 'Drivers' that provide services to your application
- Model drivers can participate directly in the simulation by modifying objects
- View drivers can inject input into the simulation, and display the simulation data
- Technically, your simulation code is run in a special JavaScript driver
- Components are reusable simulation objects

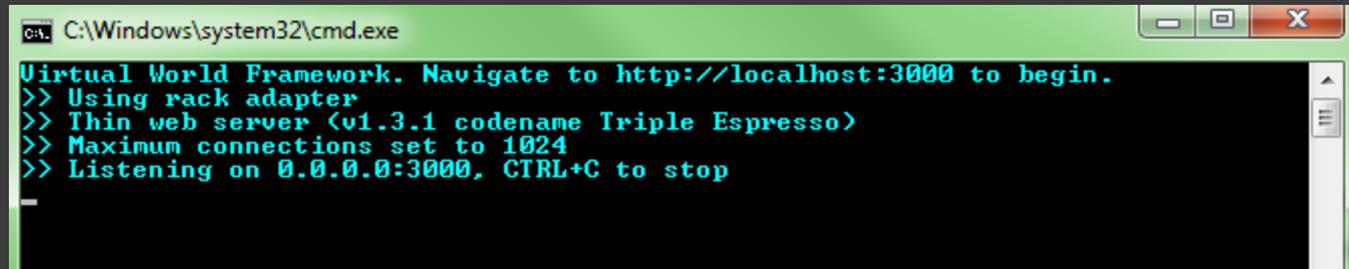

Creating an Application

Overview

- ⦿ Download and setup the server
 - The server is a Ruby application
 - Instructions are available on the website
- ⦿ Create a folder in the server's 'public' area
 - The name of the folder is the name of the application
- ⦿ Author the simulation logic in a YAML file in the directory
 - Should be called 'index.vwf'
 - This file will be served to the client when they connect to an instance of the application
- ⦿ Browse to the server URL, then to the name of your folder
 - The system will create and load a new instance of the application

Run the VWF Server

- ◎ Download the latest release:
 - virtualworldframework.com/web/downloads.html
- ◎ Extract the contents from the zip
- ◎ Double-click run.bat to start the server

```
C:\Windows\system32\cmd.exe
Virtual World Framework. Navigate to http://localhost:3000 to begin.
>> Using rack adapter
>> Thin web server (v1.3.1 codename Triple Espresso)
>> Maximum connections set to 1024
>> Listening on 0.0.0.0:3000, CTRL+C to stop
```

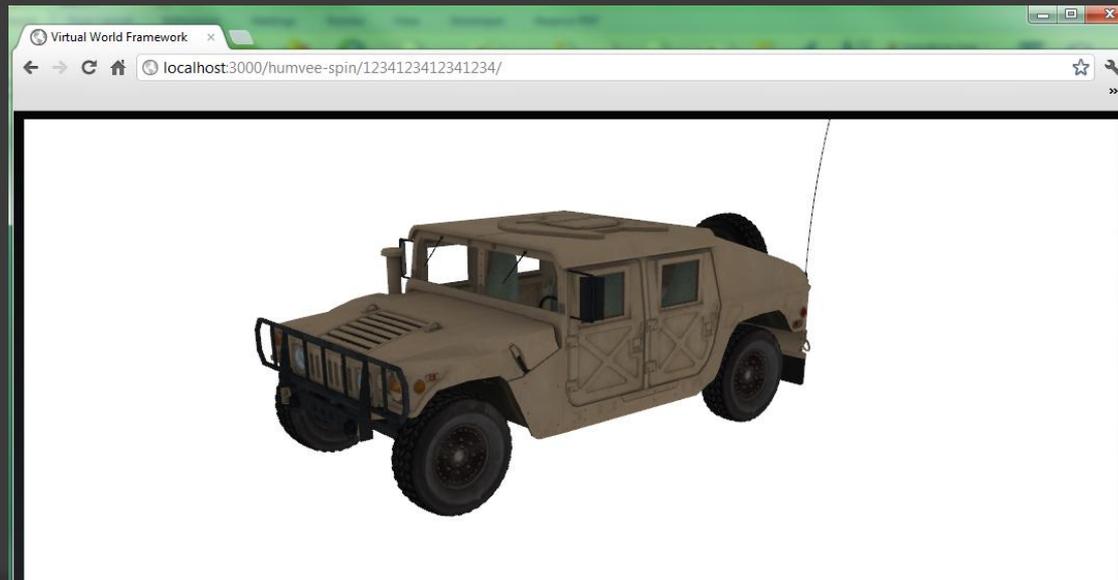

Author Logic

- ⦿ Model file is a YAML document
- ⦿ Hierarchical structure
- ⦿ extends / implements keywords for reuse of components
- ⦿ Can consist of:
 - properties
 - children
 - methods
 - events

```
index.vwf.yaml x
1 ---
2 extends: http://vwf.example.com/navscene.vwf
3 properties:
4   ambientColor: [ 183, 183, 183 ]
5 children:
6   humvee:
7     extends: http://vwf.example.com/node3.vwf
8     source: humvee.dae
9     type: model/vnd.collada+xml
10    implements:
11      - http://vwf.example.com/spin-on-click.vwf
12    scripts:
13      - |
14        this.initialize = function() {
15          this.camera.translation = [ -320, -360, 164 ];
16          this.camera.lookAt = this.humvee.id;
17          this.camera.far = 3000;
18        }
```

Run the Application

- ① Open the application URL in the browser
 - `vwf_server_IP:Port/application_folder_name`
- ② Appends auto-generated instance ID
 - Full URL can be passed to multiple clients

Putting the Virtual World in VWF

Building an environment....

- ⦿ The VWF is a framework!
- ⦿ Serves as a solid foundation for multi-user web applications
 - It could be used for anything from an OpenSim like environment to a collaborative spreadsheet
- ⦿ Further work required to build a virtual environment
 - Need to develop drivers to support traditional virtual world features and interactions
 - Avatars
 - Terrain
 - Weather
 - Materials and behaviors
 - Asset marketplace
 - User profiles and sign in
 - Persistence of world state

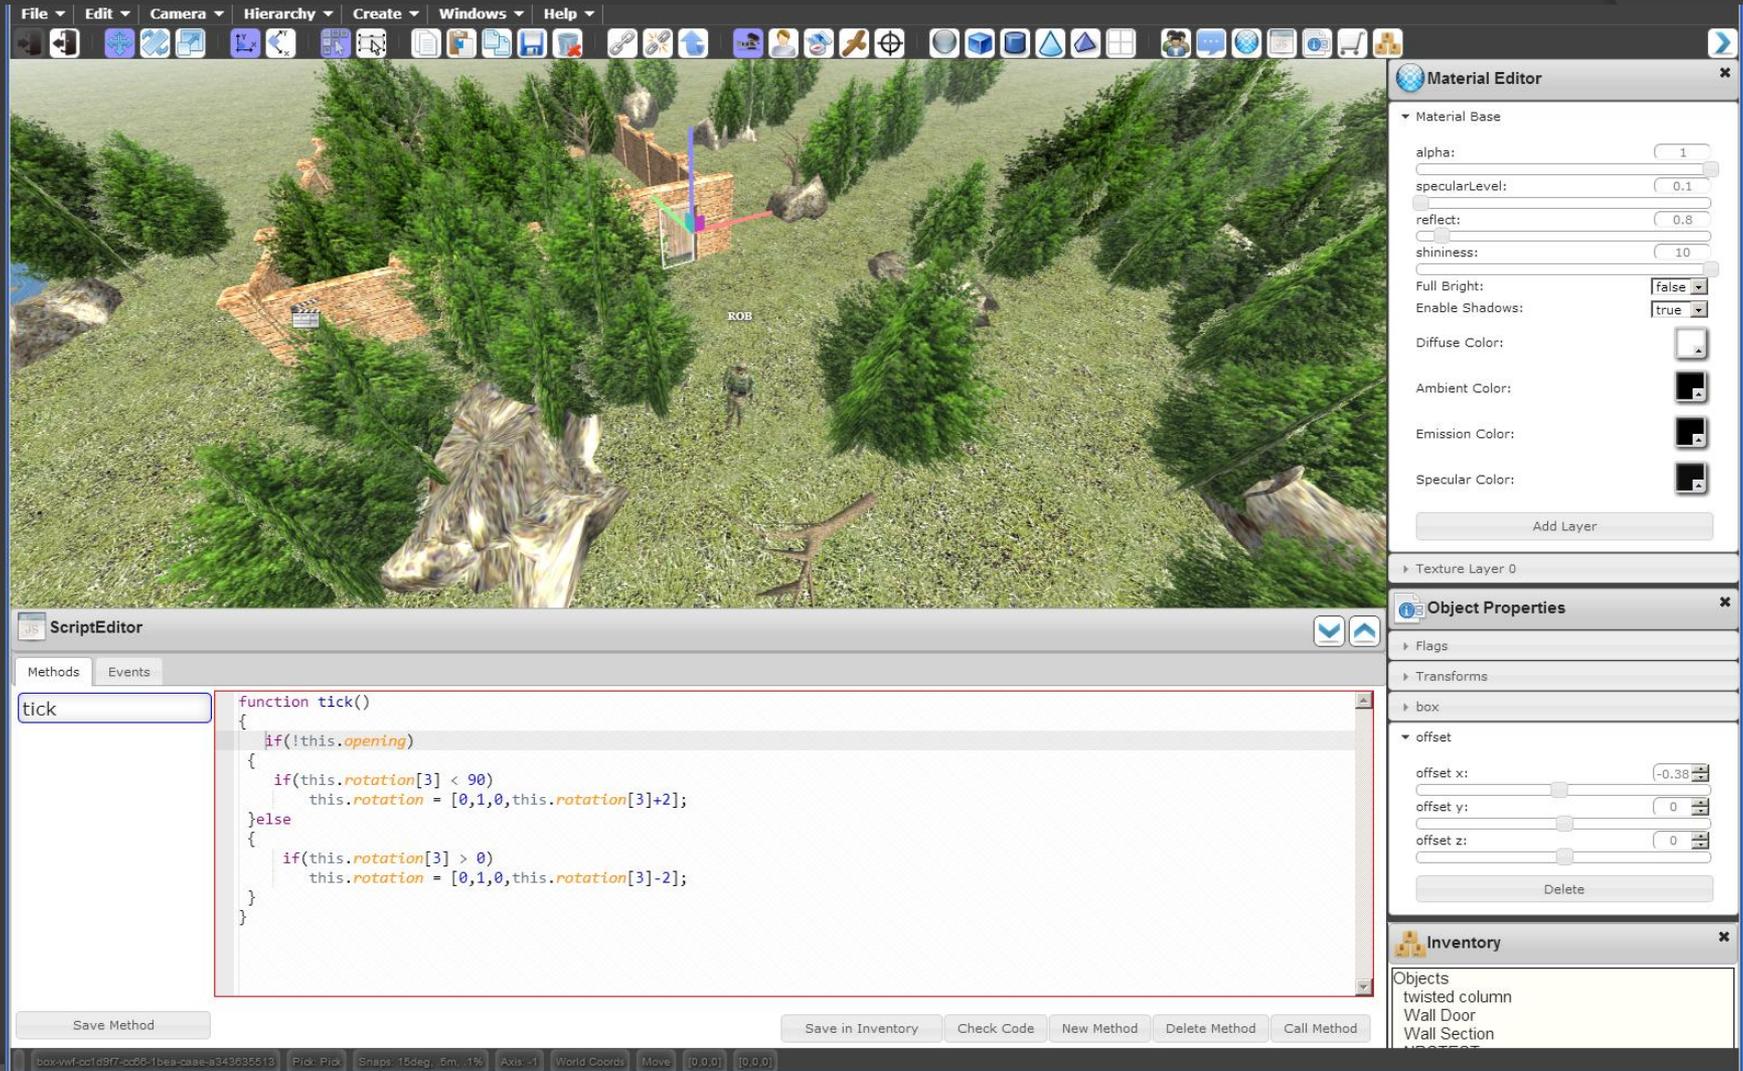

Progress

- ADL and OSD are researching many of these topics
- We're building a 'proof of concept' environment demonstrating many of these features
- Currently, it needs several security and usability enhancements before public release
- However, we're confident that the VWF serves as a solid foundation for development, and that a virtual environment can be built in the VWF

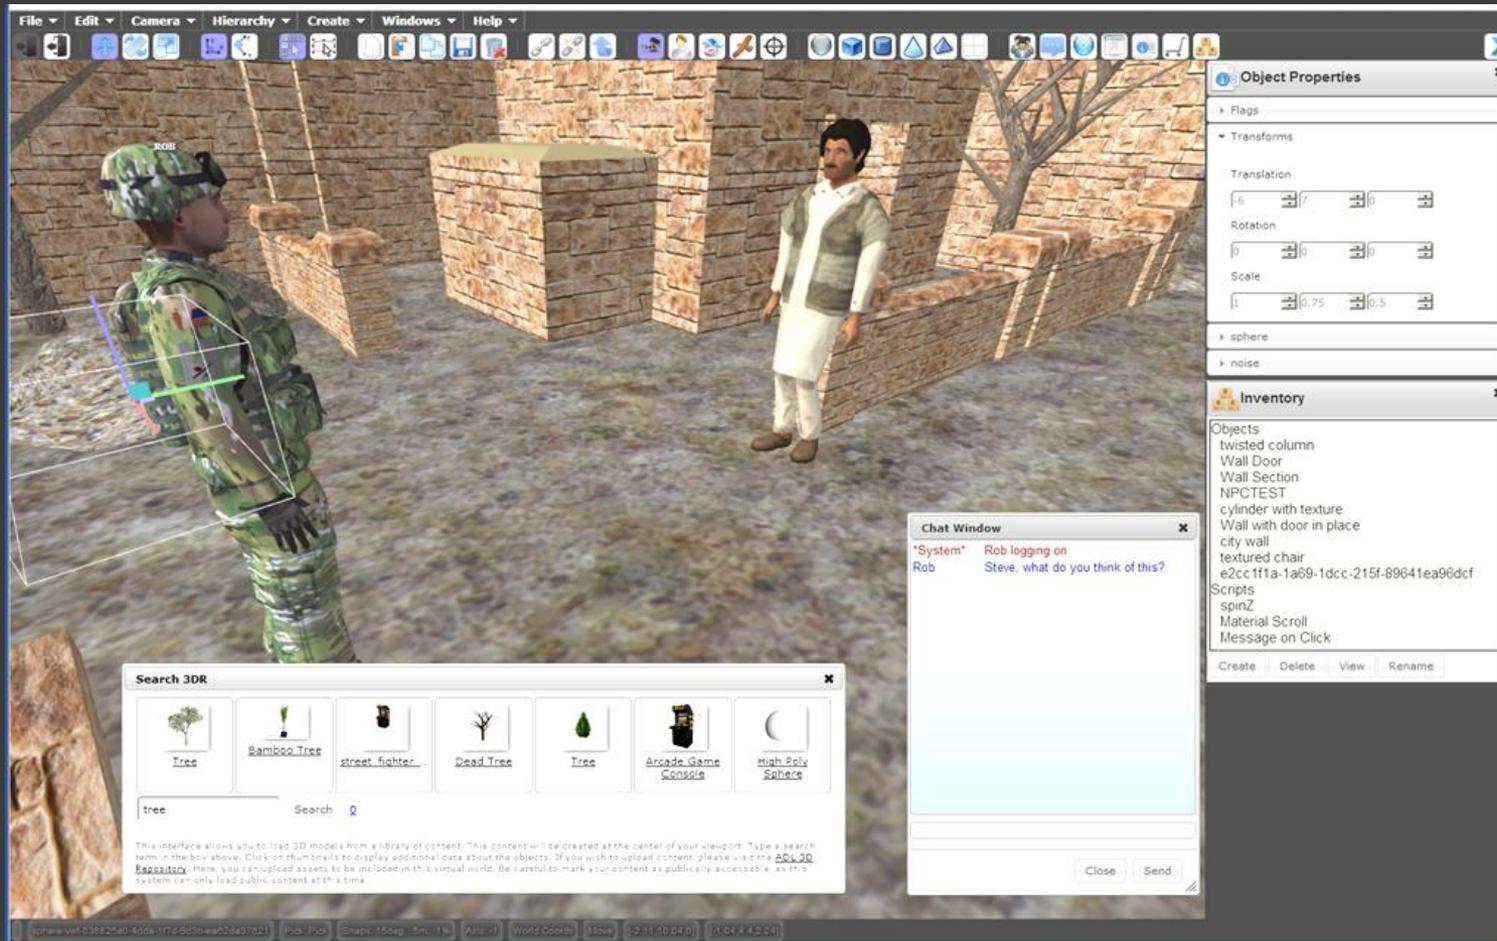

Demo Features

- Integration with the ADL 3DR for searching and loading assets
- Prototype persistence service for world state
- Basic avatar motion
- Camera modes
- Object and material editing
- Scripting
- Demo User profile and sign in service
